(57) Abstract :

The present invention discloses a smart eye glass device and a method for assisting a visually impaired user. The device comprises a wearable frame having a front frame portion and temple arms, wherein a housing mounted on the front frame portion encloses a forward-facing camera for passive image capture. A central processing unit connected to the camera processes captured image frames to identify physical objects within a forward field of view using geometric and appearance-based feature extraction. The processing unit further computes an estimated distance of each identified object from the user based on calibrated monocular camera parameters and image-plane measurements, and generates spoken auditory notifications conveying object identity and distance in real time. A rechargeable power supply module integrated within a temple arm enables portable operation. An audio output interface provides speech-based cues near the user's ear, while a tactile push-button input allows mechanical toggling of device operational states.
